VPN Connectivity Runbook

Incident class: INC-9842 · Site-to-site tunnel instability

1. Confirm the reported symptom

- Ask the requester which service is unreachable and since when.
- Record the affected device, user, floor and local time.
- Check the tunnel state on the concentrator: expected value is QM_IDLE or ESTABLISHED.
- Do not reset the tunnel until the current state has been captured.

2. Verify connectivity

- Ping the aggregation gateway from the Floor 42 edge switch.
- Trace the path to the remote peer and confirm the hop where latency spikes.
- Compare interface error counters before and after the test.

3. Apply the approved remediation

- Renegotiate the tunnel during the approved maintenance window.
- Pin the IKE identity to the primary peer only while the aggregation link is unstable.
- Confirm the session table repopulates and the trading feed reconnects.
- Capture the before and after output as evidence on the ticket.

4. Verify restoration and document

- Requester confirms the service is working.
- Record root cause, work performed and verification in the resolution notes.
- Attach the captured evidence and the change record reference.
- Link this runbook article to the mission trail.

Escalate to Network Operations if the tunnel drops twice in one maintenance window.
